Background Computed tomography (CT) is a type of medical imaging that uses x-rays to generate cross-sectional images of the body. Although CT improved the limitations in conventional radiography, the effective dose for CT procedures is higher than the dose of a conventional radiographic examination of the same part. For instance, the radiation dose for kidney, ureter, and bladder (KUB) in conventional radiography is 0.7 mSv, whereas in the CT scan it is 10 mSv. Therefore, patient radiation safety in compliance with American College of Radiology (ACR) standards has to be maintained. In this study, we aimed to evaluate the patient radiation dose delivered in unenhanced CT-KUB examinations using two CT machines at King Abdulaziz Medical City in Jeddah (KAMC-JD).

Methods This was a retrospective, cross-sectional study of all patients who had unenhanced CT-KUB examinations in KAMC-JD between 1 January and 30 June 2018. Patient characteristics and radiation parameters were obtained from the hospital information system and pictures archiving and communication system, respectively, and compared with the ACR standards.

Results A total of 264 patients were included in the study: 199 (75.5%) examinations were performed with machine 1 and 65 (24.6%) were performed with machine 2. Mean age was 48.1±16.3 years and 66.7% of patients were male. Mean body-mass index (BMI) was 29.59±6.45 kg/m². The mean volume CT dose index (CTDIvol), dose-length product (DLP), time(s), pitch, and effective dose were significantly different in the CT machines with p values between 0.004 and <0.001. No significant differences were found in kVp, slice number, slice thickness, length of cover, and effective dose with use of different types of CT. Both CT machines were within the ACR standard range of 10mSv. There was a positive strong correlation between BMI (29.6 kg/m²) and the effective dose (p<0.001).

Conclusion The radiation doses delivered by the two CT scanners in KAMC-JD are compliant with ACR standards. Periodic assessment is recommended every 2 years.

OUTPATIENT FOLLOW-UP IS ASSOCIATED WITH REDUCED EMERGENCY DEPARTMENT VISITS IN PATIENTS WITH SICKLE CELL DISEASE: A RETROSPECTIVE COHORT STUDY FROM RIYADH, SAUDI ARABIA

Rana Ahmed Saleh, Lama Alhmaly, Ramesh Vishwakarma, Ismat Kamran, Moussab Damlaj, Ahmed Alaskar, Giamal Edin Gmati. Medicine Department, King Abdulaziz Medical City, National Guard Health Affairs

Background Pain is the main source of distress in patients with sickle cell disease (SCD). Unmanageable pain, often termed ‘crises’, may prompt unexpected visits to the emergency department (ED) or other acute healthcare facilities. One study from the Eastern Province in Saudi Arabia reported that 64% of patients with SCD present to the ED more than three times over a 6-month period. Outpatient follow-up may have a role in preventing ED visits, but this has not been fully explored in Saudi Arabia. This study aimed to assess the relation between outpatient follow-up and future ED visits due to painful crises in patients with SCD.

Methods This retrospective, observational study utilized data from the electronic medical record system at King Abdulaziz Medical City, National Guard Health Affairs in Riyadh. The study included adult patients with SCD who presented at least once to the ED due to a painful crisis between January 2016 and December 2017. The time between ED visits due to painful crises was set as the outcome variable. Cox regression analysis with random effects model (frailty model) was used to determine the effect of outpatient follow-up at 15 days, 30 days, and 90 days on the time to next ED visit. Baseline characteristics and previous history of sickle cell complication were included in the model as confounders.

Results Eighty patients with SCD presented a total of 463 times to the ED due to painful crises. 54% of these visits
required admission and resulted in a total length of stay of 1474 hospital days and 49 ICU days. Attendance at a hematology outpatient clinic within 30 days from discharge significantly reduced the hazard of an ED visit due to a painful crisis compared with no follow-up (hazard ratio 0.70, 95% CI 0.52–0.94, p=0.02).

Conclusion Appropriate outpatient referral at discharge may be associated with decreased ED visits. These benchmark results invite further investigation into the effects of outpatient management on preventing painful crises in patients with SCD.

Opioid consumption:
- Consumption of opioids decreased by 33% for meperidine 100 mg and by 41.6% for meperidine 50 mg. Consumption significantly decreased by 54% for tramadol capsules and by 33% for tramadol injection.

Cost saving:
- The cost saved after implementation of the clinical pathway is more than 410,709 SR.

Conclusion Proper pain management for patients with SCD leads to a significant decrease in ED visits, and reduces hospital admissions and readmission rates. Consequently, more than 400,000 SR was saved after the implementation of the pathway. We believe that physicians, nurses, and patient education sessions played a critical role in the success of the clinical pathway.

Methods A clinical pathway for the management of SCD acute painful crisis has been initiated at KFAFH in Jeddah. The main objectives of this clinical pathway management were to unify practice, standardize care, and promote judicious use of opioids at KFAFH. The aims of this study were:
- To reduce the rate of ER visits per patient by more than 50% within 1 year.
- To decrease the rate of admissions per patient and readmission rates by more than 30% and 40%, respectively, within 1 year.
- To reduce the consumption of meperidine and tramadol by more than 25% and 40%, respectively, within 1 year as a secondary outcome.

Results ED visits:
- The annual rate of ED visits per patient dropped by 75.55% (45 versus 11.5).
- There was a progressive reduction in the frequency of ED visits over the year.

Admission rate:
- The rate of admissions per patient dropped by 41.87%.
- The readmission rate declined by 54.51%.

Opioid consumption:
- Consumption of opioids decreased by 33% for meperidine 100 mg and by 41.6% for meperidine 50 mg. Consumption significantly decreased by 54% for tramadol capsules and by 33% for tramadol injection.

Cost saving:
- The cost saved after implementation of the clinical pathway is more than 410,709 SR.

Conclusion Proper pain management for patients with SCD leads to a significant decrease in ED visits, and reduces hospital admissions and readmission rates. Consequently, more than 400,000 SR was saved after the implementation of the pathway. We believe that physicians, nurses, and patient education sessions played a critical role in the success of the clinical pathway.
